

# Resonance Behaviour of a Pulsed Electronic Control Gear for Dielectric Barrier Discharges

Michael Meisser, Mark Paravia, Wolfgang Heering, Rainer Kling

Light Technology Institute [LTI], Department of Electrical Engineering and Information Technology

# Dielectric Barrier Discharge Lamps - DBD

**coaxial type**

Xeradex® (OSRAM, Germany)

**plane to plane type**

Planilum® (Saint-Gobain Glass, France)

## features:

- instant-on
- long lifetime
- areal radiation
- various wavelengths
- mercury free

## applications:

- UV - surface modification, lacquer curing
- scanner and copying machines  
e.g. XeFI™ (OSRAM, Germany)
- ambient lighting

# Dielectric Barrier Discharge Lamps – Set-up

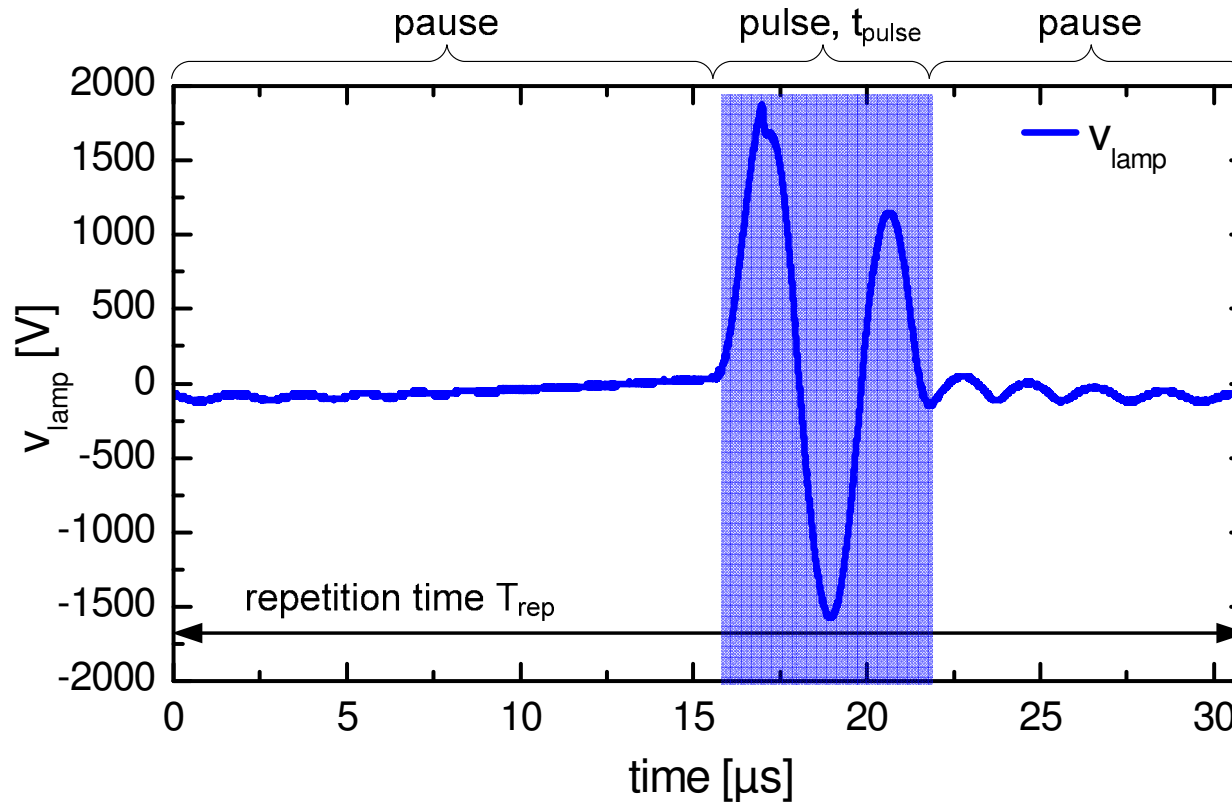

## Characterization:

- low power factor – capacitive loads

## Requirements:

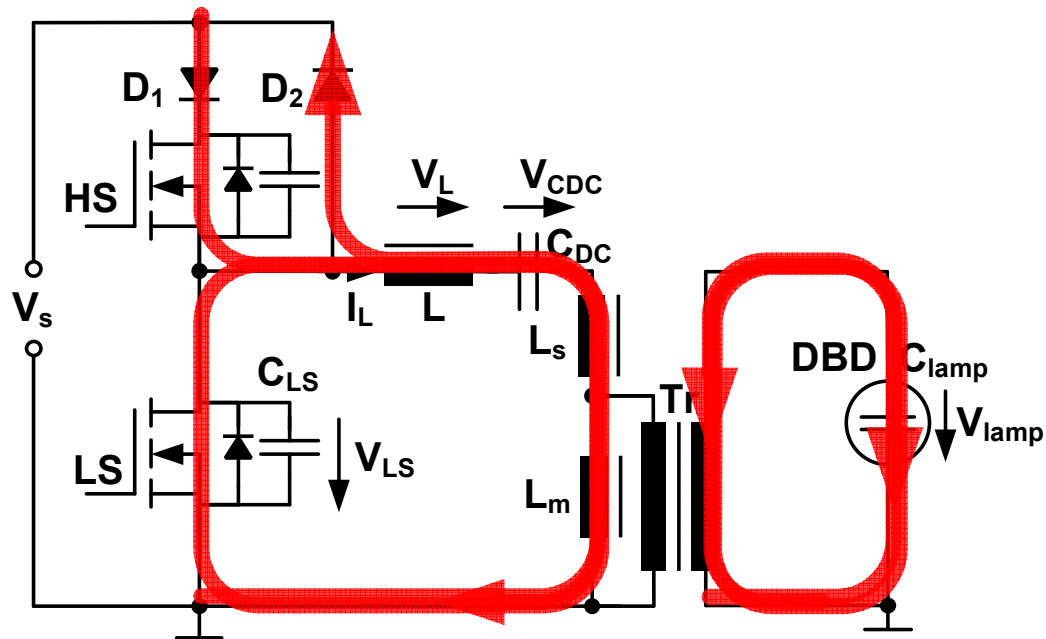

- high AC voltage
- pulsed operation
- energy recovery

# Pulsed Operation Mode With Resonant ECG

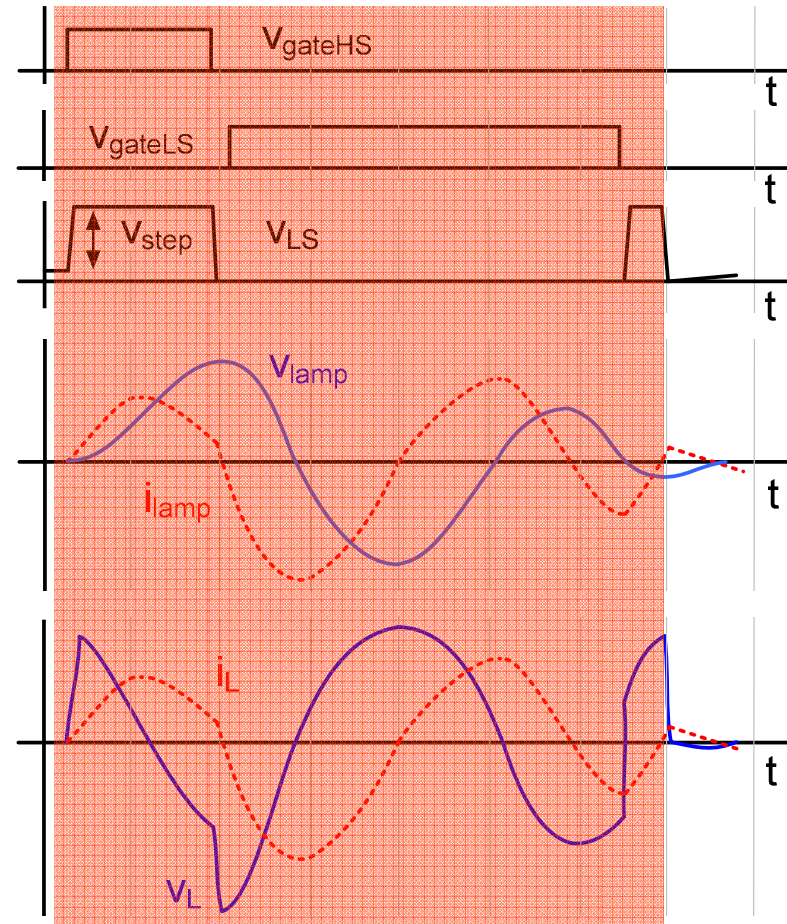

- 3 half-wave sinusoidal pulse lamp operation
- one lamp ignition per half-wave
- $f_{\text{pulse}} \approx 200 \text{ kHz}$ ,  $f_{\text{rep}} = 32 \text{ kHz}$

# Schematic and Operation Mode

- resonant tank excited by half-bridge
- waveforms resulting from step answer of RLC-circuit

Paravia, M. et al "Threshold current density for homogeneous excitation of pulsed xenon excimer DBD." *Int. Conf. on Plasma Science, ICOPS, 2008*

# Problem of Parasitic Parallel Resonance

- excessive v-t products
- magnetic runaway of magnetic components
- peak currents may destruct half-bridge

# Origin of Parasitic Parallel Resonance

- parasitic parallel resonance between  $L_m$  and  $C_{lamp}$
- remaining v-t product in transformer
- charges on switch output capacitances
- stored energy on  $C_{DC}$
- level shifting: free swinging

# Managing Parasitic Parallel Resonance

■ energy left in circuit

■ circuit not clamped

**free swinging of damped  
multi-resonant circuit**

**damping by  
adjusting**

**component  
parameters**

**timing**

# Damping by Parameter Variation

- reduction of quality factor of parasitic parallel resonance

- lamp capacitance fixed by application
- transformer optimized and fixed by v-t rating
- transistors fixed by max currents
- DC-blocking capacitor
  - low damping possible to cost of reduced ignition support

# Alternatives

**parameter variation  
not an option**

**repetition  
period**

**switching  
pattern**

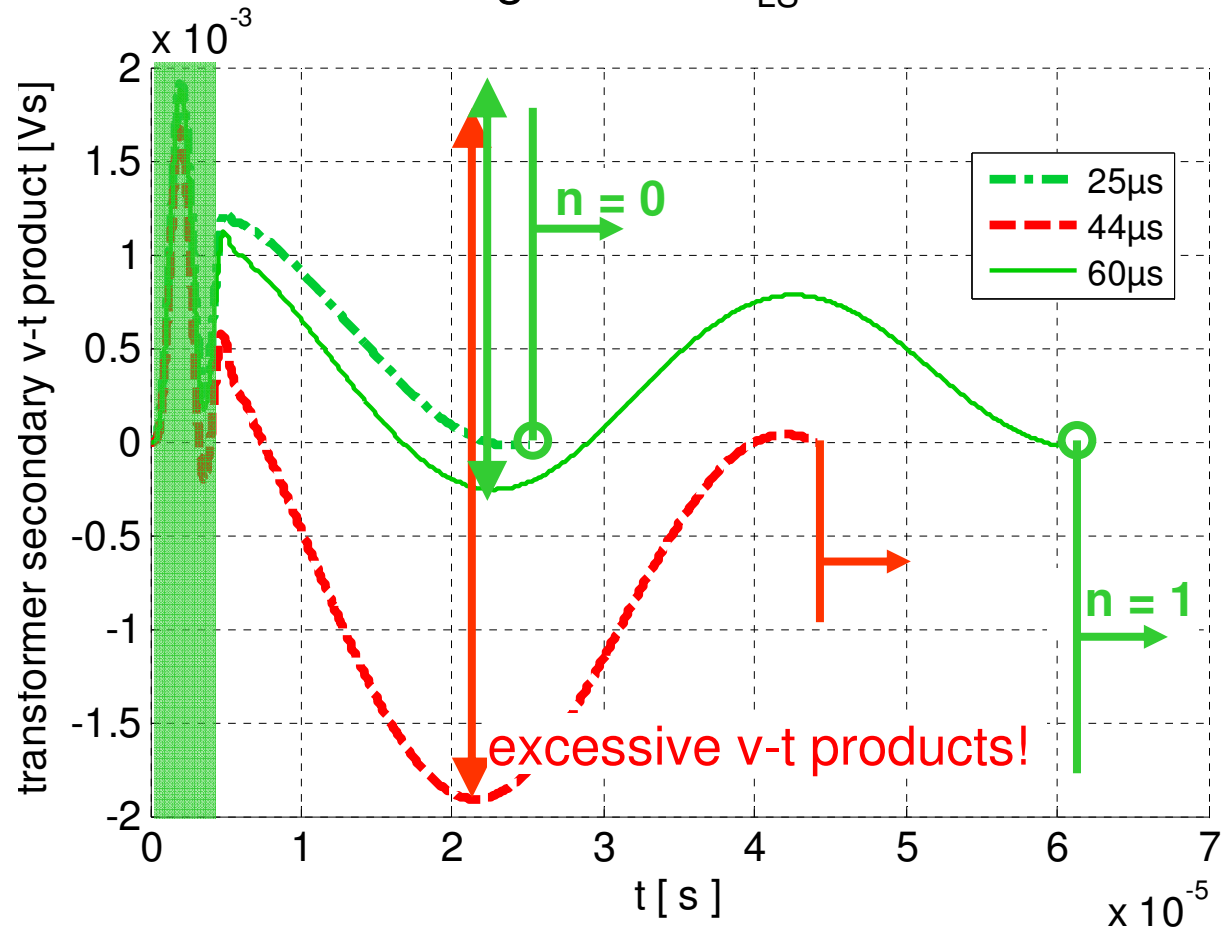

# Adjusting Repetition Period

- optimize preconditions for next pulse
- pulse start in minimum of volt-second swing – initial  $V_{LS}$  minimal

therefore meet:

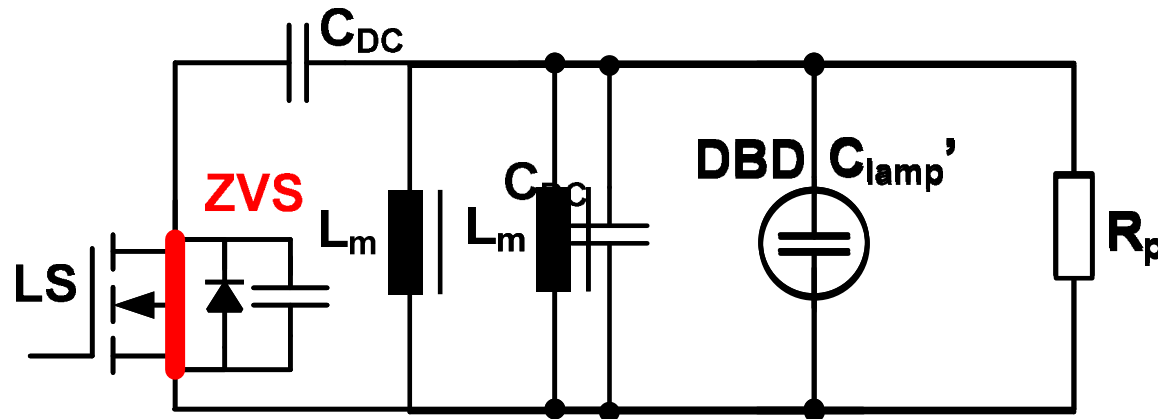

$$T_{rep} \approx \frac{1 + 2n}{2 \cdot f_{pp}} + t_{pulse}$$

- reduced v-t product swing
- reduced amplitude of resonance

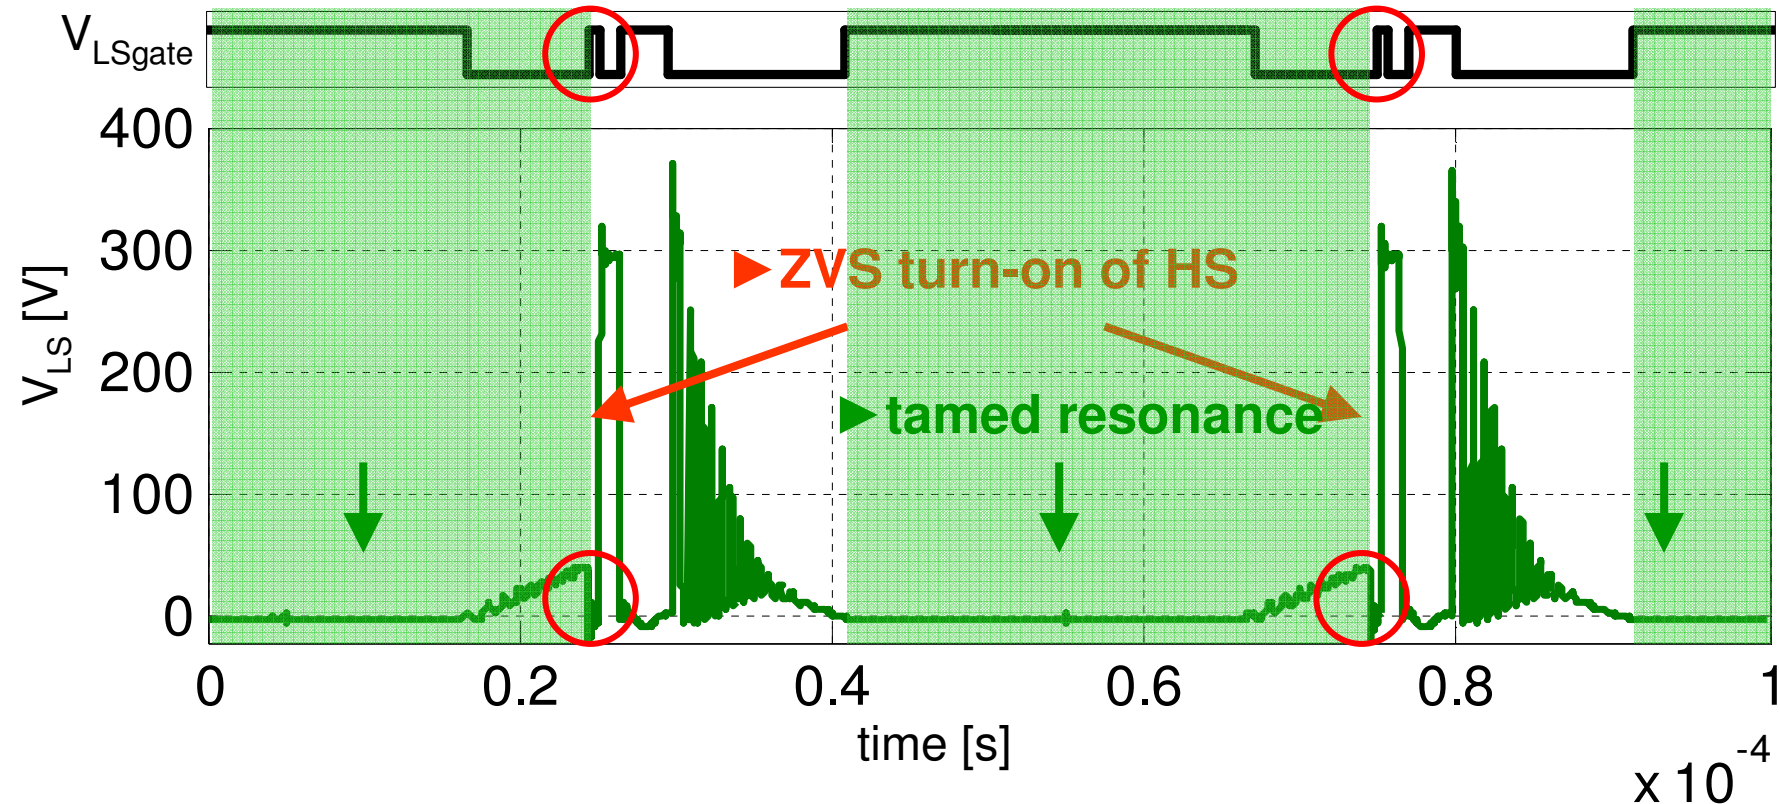

## Variation of Switching Pattern

- keeping LS on during pulse pause

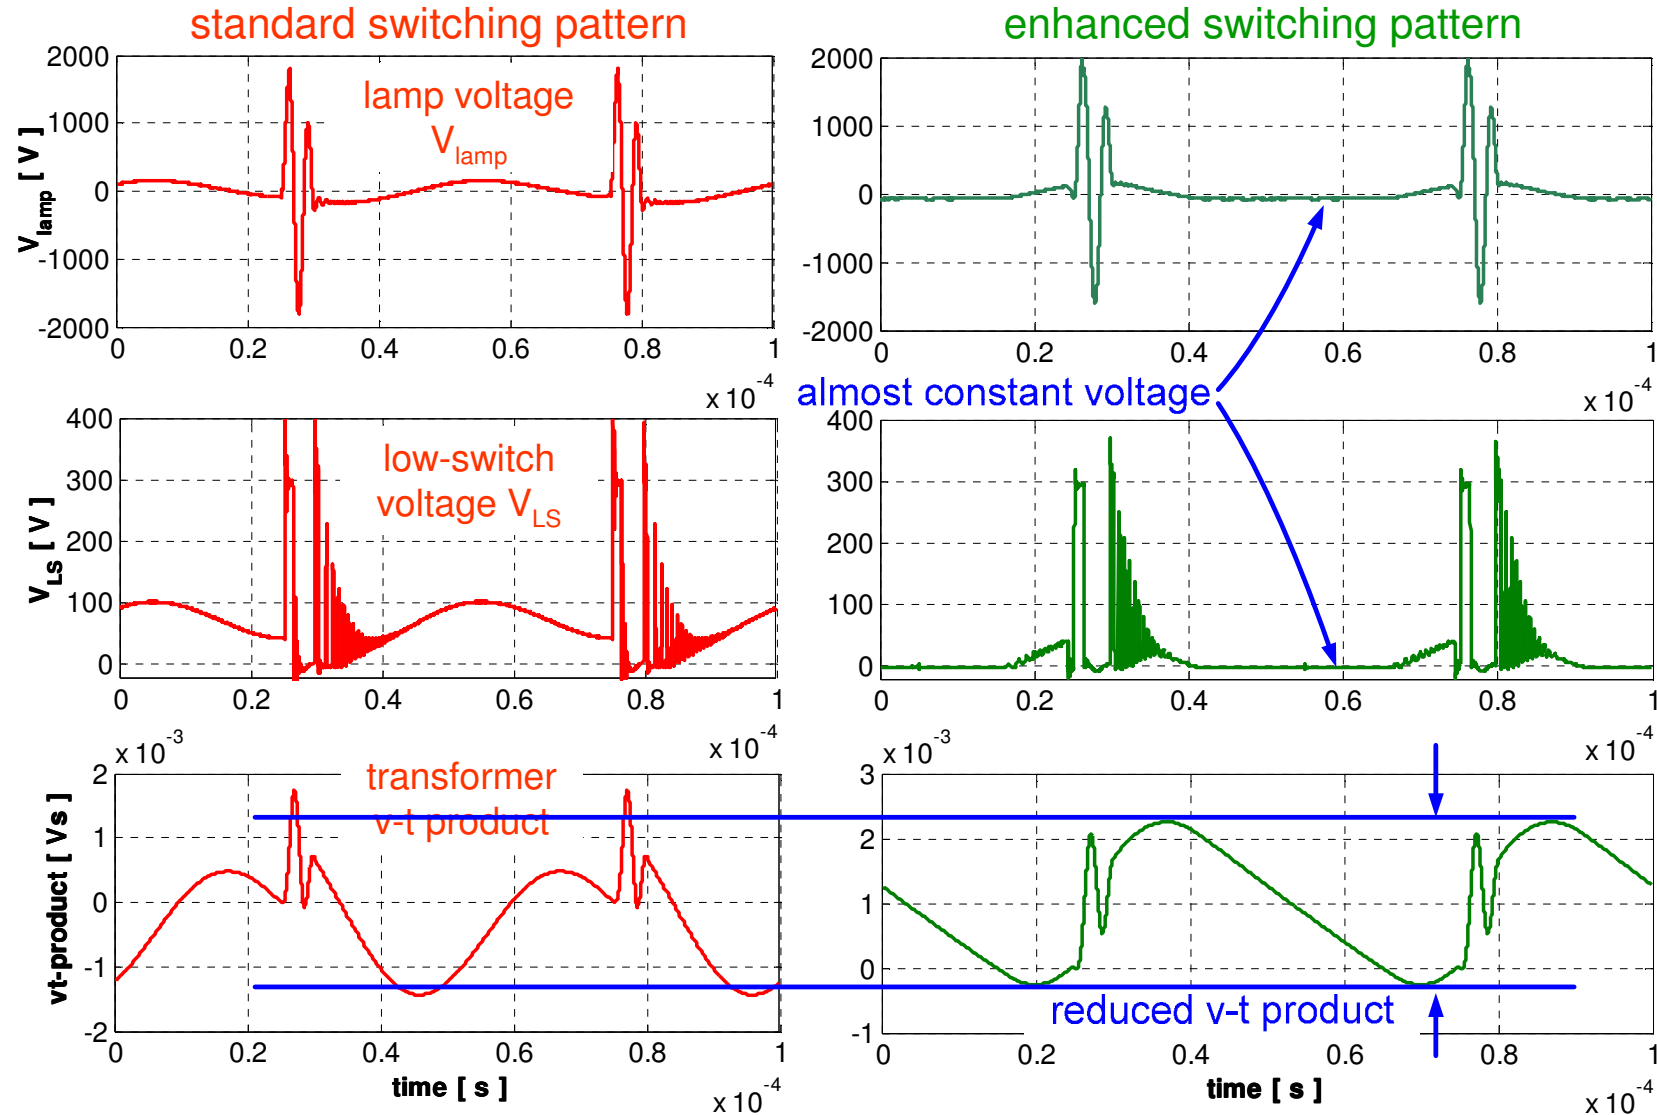

- result:
  - reduced resonance frequency
  - $v_{C_{DC}}$  constant and adequate to compensate v-t product
- benefits:
  - lower v-t products reduce losses & prevent saturation of transformer
  - parasitic parallel resonance tamed

# Additional Benefit: ZVS for HS On-Transition

- keeping LS on during pulse pause but opened prior to next pulse
- short closing directly before pulse stores energy in L
- utilization of  $E_L$  to charge  $C_{HS}$  ► **efficiency increase from 80 % to 82 %**

# Comparison of switching patterns

# To Conclude

- resonant ECG drives DBD lamp

- serious problem of parasitic parallel resonance

- adaption of repetition period  $T_{rep}$  shrinks resonant amplitude

- advanced switching scheme tames negative effects and brings additional benefit  
▶ **increased reliability & efficiency + 2 %**
